## 1. INTRODUCTION TO THE GENERAL FORMALISM: 5/8/17

Today, Adrian spoke about what a spectral sequence is and where they come from. The next four lectures will be interesting examples, even if today is somewhat dry.

**Definition 1.1.** A **(homological) spectral sequence** is the data of

- modules over a ring<sup>1</sup>  $E_{p,q}^r$  indexed by  $r \geq N$  for some positive  $N$  and  $p, q \in \mathbb{Z}$ , and
- maps  $d_r: E_{p,q}^r \rightarrow E_{p-r, q-1+r}^r$ , called **differentials**,

subject to the following conditions:

- $d_r^2 = 0$ , and
- for all  $p, q$ , and  $r$ ,  $E_{p,q}^{r+1}$  is the homology of the chain complex  $(E_{p-r\bullet, q-1+r\bullet}^r, d_r)$  at  $E_{p,q}^r$ .

The way in which the differentials affect the grading is pretty opaque, so let's see what it looks like for small  $r$ .

$$\begin{array}{ccccc}
 E_{p,q}^0 & & & & E_{p-2,q+1}^2 \\
 \downarrow d_0 & & & & \nwarrow d_2 \\
 E_{p,q-1}^0 & & E_{p-1,q}^1 \xleftarrow{d_1} E_{p,q}^1 & & E_{p,q}^2
 \end{array}$$

The differentials swing from downward to leftward, and comes closer and closer to pointing northwest.

This is a lot of structure, and one usually visualizes it as a book, with **pages**  $E_{\bullet,\bullet}^r$ , and each page is thought of as a lattice with the differentials:

$$\begin{array}{ccccccc}
 & & \vdots & & \vdots & & \vdots \\
 & & & & & & \\
 \cdots & \xleftarrow{d_r} & E_{p+1,q-1}^r & \xleftarrow{d_r} & E_{p+1,q}^r & \xleftarrow{d_r} & E_{p+1,q+1}^r & \cdots \\
 & & \nwarrow & & \nwarrow & & \nwarrow \\
 \cdots & \xleftarrow{d_r} & E_{p,q-1}^r & \xleftarrow{d_r} & E_{p,q}^r & \xleftarrow{d_r} & E_{p,q+1}^r & \cdots \\
 & & \nwarrow & & \nwarrow & & \nwarrow \\
 \cdots & \xleftarrow{d_r} & E_{p-1,q-1}^r & \xleftarrow{d_r} & E_{p-1,q}^r & \xleftarrow{d_r} & E_{p-1,q+1}^r & \cdots \\
 & & \vdots & & \vdots & & \vdots
 \end{array}$$

<sup>1</sup>In the general setup, one has to be somewhat agnostic about what these are: in any context where one can do homological algebra, one can define spectral sequences: abelian groups, modules over a ring, objects in an abelian category...

The point of this heavy machinery is that there's a machine which takes filtered objects and functors satisfying an excision property to spectral sequences, and such pairs arise in many contexts in algebra, topology, and geometry.

**Definition 1.2.** Let  $\mathbb{Z}$  denote the **poset category** of the integers, i.e. there's a unique arrow  $m \rightarrow n$  iff  $m \leq n$ . Then, a **filtered object** in a category  $\mathcal{C}$  is a functor  $X: \mathbb{Z} \rightarrow \mathcal{C}$ .

The idea is a topological space  $X$  together with inclusions  $X_i \hookrightarrow X_{i+1}$ , such that  $X$  is the union of all of the  $X_i$ . More generally, one can let  $X$  be the colimit over  $i$  of  $X(i)$ . One example is the CW filtration of a CW complex  $X$ , where  $X(n)$  is the  $n$ -skeleton of  $X$ .

**Definition 1.3.** Let  $\mathcal{C}$  be either  $\mathbf{Top}_*$ , the category of pointed topological spaces, or  $\mathbf{Ch}(\mathbf{Mod}_A)$ , the category of chain complexes of  $A$ -modules for a ring  $A$ .

- Let  $f: X \rightarrow Y$  be a  $\mathcal{C}$ -morphism, so that we can take its mapping cone  $C_f$  and obtain a sequence  $X \rightarrow Y \rightarrow C_f$ . If we iterate this construction,  $C_{Y \rightarrow C_f}$  is weakly equivalent to  $\Sigma X$ , and the mapping cone of this is weakly equivalent to  $\Sigma Y$ , so we obtain a sequence

$$X \xrightarrow{f} Y \longrightarrow C_f \longrightarrow \Sigma X \xrightarrow{\Sigma f} \Sigma Y \longrightarrow \Sigma C_f \longrightarrow \dots$$

Such a sequence is called a **cofiber sequence**.<sup>2</sup>

- A **functor satisfying excision** is a covariant or contravariant functor  $\mathcal{C} \rightarrow \mathbf{Ab}$  taking cofiber sequences to long exact sequences.<sup>3</sup>

To see why  $C_{Y \rightarrow C_f} \simeq \Sigma X$ , one can work with particularly nice maps, so that  $Y \rightarrow C_f$  is an injection, and its mapping cone crushes  $Y$  to a point, producing  $\Sigma X$ . The cofiber  $C_f$  is the topological analogue of the quotient  $Y/X$ .

**Example 1.4.** Here are some examples of these functors. First, let  $\mathcal{C} = \mathbf{Top}_*$ :

- (1) Covariant functors  $\mathbf{Top}_* \rightarrow \mathbf{Ab}$  with excision include homology functors  $H_n$ .
- (2) For covariant functors sending fiber sequences to long exact sequences, we have homotopy groups  $\pi_i$ .
- (3) Contravariant functors with excision include cohomology functors  $H^n$ .

For the category of chain complexes, cofiber and fiber sequences are the same thing.

- (4) Covariant functors include homology and covariant derived functors such as  $\mathrm{Ext}^i(M, -)$  and  $\mathrm{Tor}_i(M, -)$ .
- (5) Contravariant functors include cohomology and contravariant derived functors such as  $\mathrm{Ext}^i(-, M)$ . ◀

From here, one can draw picture of the argument for why such a functor defines a spectral sequence:

(Diagram to be made later.)

From this diagram, one can see how the differentials arise, and they have the grading for the  $E_2$  page. In particular, given the filtration  $\{X_p\}$  of  $X$ , we can let  $E_{p,q}^2 := H_{p+q}(X_p)$ .<sup>4</sup> Thus the  $E^1$  page is

$$\begin{array}{ccccc} \vdots & & \vdots & & \vdots \\ & & & & \\ H_2(X_0) & \xleftarrow{d_1} & H_3(X_1) & \xleftarrow{d_1} & H_4(X_2) \leftarrow \dots \\ & & & & \\ H_1(X_0) & \xleftarrow{d_1} & H_2(X_1) & \xleftarrow{d_1} & H_3(X_2) \leftarrow \dots \\ & & & & \\ H_0(X_0) & \xleftarrow{d_1} & H_1(X_1) & \xleftarrow{d_1} & H_2(X_2) \leftarrow \dots \end{array}$$

<sup>2</sup>You may prefer to call this a **cofibre sequence**.

<sup>3</sup>There's a version of this for functors taking fiber sequences to long exact sequences, but we won't need to use it.

<sup>4</sup>Technically, we started only with one functor  $H$ , but we can define  $H_{n-1}(X) := H_n(\Sigma X)$  and extend to a family of functors, just as for homology.

The key is explaining how the differentials occur. Let  $h$  be a homology theory,  $X = \{X_i\}$  be a filtration, and  $C_i := X_i/X_{i-1}$  be the cofibers. Then we have a diagram

$$\begin{array}{ccccccc} & & h(C_1) & \longleftarrow & h(C_2) & \longleftarrow & h(C_3) \\ & & \uparrow & & \uparrow & & \uparrow \\ h(X_0) & \longrightarrow & h(X_1) & \longrightarrow & h(X_2) & \longrightarrow & h(X_3) \longrightarrow \dots \end{array}$$

Any pair  $\rightarrow, \uparrow$  fits into a long exact sequence with connecting morphism  $\delta: h(C_i) \rightarrow h(\Sigma X_{i-1})$ :

$$\begin{array}{ccccccc} & & h(C_1) & \longleftarrow & h(C_2) & \longleftarrow & h(C_3) \\ & \swarrow \delta & \uparrow & \swarrow \delta & \uparrow & \swarrow \delta & \uparrow \\ h(X_0) & \longrightarrow & h(X_1) & \longrightarrow & h(X_2) & \longrightarrow & h(X_3) \longrightarrow \dots \end{array}$$

This is how the first differentials arise: take the connecting morphism  $\delta$ , then map back  $h(X_{i-1}) \rightarrow h(C_{i-1})$ . Considering longer sequences of maps after taking homology gives you the higher-order differentials.

What follows was a complicated diagram chase that was hard to live-T<sub>E</sub>X.

We had the  $E^1$  page and differentials, and after taking homology, we get the  $E^2$  page:

$$\begin{array}{ccccc} & E_{0,2}^2 & E_{1,2}^2 & E_{2,2}^2 & \\ & \swarrow & \swarrow & \swarrow & \\ & E_{0,1}^2 & E_{1,1}^2 & E_{2,1}^2 & \\ & \swarrow & \swarrow & \swarrow & \\ & E_{0,0}^2 & E_{1,0}^2 & E_{2,0}^2 & \end{array}$$

## 2. THE ATIYAH-HIRZEBRUCH SPECTRAL SEQUENCE: 5/9/17

Today, I'm going to talk about the Atiyah-Hirzebruch spectral sequence. Last time, we talked about how to construct a spectral sequence from a filtration of a topological space; today, we'll black-box that construction and use it to compute some stuff. Namely, we'll use the CW fibration associated to any CW complex.

Let  $E^*$  be a generalized cohomology theory and  $X$  be a CW complex. The **Atiyah-Hirzebruch spectral sequence** is a spectral sequence

$$E_2^{p,q} = H^p(X; E^q(\text{pt})) \implies E^{p+q}(X).$$

We'll explain what all this actually means.

**Convergence.** Sometimes you're reading a book and it feels like it goes on forever. It's nice when spectral sequences don't do that. As an example, we'll look at a **first-quadrant spectral sequence**, one where  $E_2^{p,q} = 0$  when  $p < 0$  or  $q < 0$ . In this setup, if you pick any  $(p, q)$ , then after finitely many pages, the differentials are so long that they leave the first quadrant, so you get a sequence  $0 \rightarrow E_{p,q}^r \rightarrow 0$ , and therefore when you take homology, nothing changes. Thus it makes sense to say what the end of the spectral sequence is.

**Definition 2.1.** Whenever it makes sense, we'll define the  $E_\infty$ -**page** of the spectral sequence to be  $E_\infty^{p,q} = E_{p,q}^r$  for  $r \gg 0$ . One says  $E_r^{p,q}$  **converges** or **abuts** to  $E_\infty^{p,q}$ .

Typically this is something interesting we want to calculate.

**Definition 2.2.** Let  $A_\bullet$  be a graded abelian group together with an exhaustive filtration  $\{F_p\}$ .

- The **associated graded** of the filtration  $\{F_i\}$  is

$$(\text{gr } A)_{p,q} := F_p A_{p+q} / F_{p-1} A_{p+q}.$$

- A spectral sequence  $E_r^{p,q}$  **converges (weakly)** to  $A_\bullet$ , written

$$E_r^{p,q} \implies A_\bullet,$$

if it has an  $E_\infty$  page and the  $E_\infty$  page is the associated graded of  $A_\bullet$ .

*Remark.* There is a notion of **conditional convergence**, due to Boardman, which essentially means “not always weakly convergent, but converges under hypotheses often met in practice.” Unfortunately, defining this precisely would be a huge digression. ◀

**Generalized cohomology theories.** The Atiyah-Hirzebruch spectral sequence is used to compute things which behave like homology or cohomology, but are slightly different: they satisfy all of the Eilenberg-Steenrod axioms except for the dimension axiom. These generalized cohomology theories have been a huge area of focus in algebraic topology in the last half century.

**Definition 2.3.** A **generalized cohomology theory** (also **extraordinary cohomology theory**) is a collection of functors  $h^n: \mathbf{Top}_* \rightarrow \mathbf{Ab}$  such that:

- Given a map  $f: A \rightarrow X$ , let  $X/A$  denote its cofiber. There is a natural transformation  $\delta: h^n(X/A) \rightarrow h^{n+1}(A)$  such that the following sequence is long exact:

$$\cdots \longrightarrow h^n(A) \xrightarrow{h^n(f)} h^n(X) \longrightarrow h^n(X/A) \xrightarrow{\delta} h^{n+1}(A) \longrightarrow \cdots$$

- $h^n$  takes wedge sums to direct sums: if  $X = \bigvee_i X_i$ , then the natural map

$$\bigoplus h^n(X_i) \longrightarrow h^n(X)$$

is an isomorphism.

The dual notion of a **generalized homology theory** is the same, except the differentials go in the other direction. This defines a reduced homology theory, i.e. one for spaces with basepoints.

**Example 2.4** ( $K$ -theory). Let  $X$  be a compact Hausdorff space. Then, the set of isomorphism classes of complex vector bundles on  $X$  is a semiring, so we can take its group completion and obtain a ring  $K^0(X)$ .

The following theorem is foundational and beautiful.

**Theorem 2.5** (Bott periodicity).  $K^0(\Sigma^2 X) \cong K^0(X)$ .

This allows us to promote  $K^*$  into a **2-periodic** generalized cohomology theory  $K^*$ , called **complex  $K$ -theory**, by setting  $K^{2n}(X) = K^0(X)$  and  $K^{2n+1}(X) = K^0(\Sigma X)$ .<sup>5</sup>

Like cohomology,  $K$ -theory is **multiplicative**, i.e. it spits out  $\mathbb{Z}$ -graded rings. However,  $K^i(X)$  is often nonzero for negative  $i$ .

**Exercise 2.6.** For example, show that as graded abelian groups,  $K^*(\text{pt}) = \mathbb{Z}[t, t^{-1}]$ , where  $|t| = 2$ .

$K$ -theory admits a few variants.

- If you use real vector bundles instead of complex vector bundles, everything still works, but Bott periodicity is 8-fold periodic. Thus we obtain a periodic, multiplicative cohomology theory called **real  $K$ -theory**, denoted  $KO^*(X)$ . Its value on a point is encoded in the **Bott song**.
- Sometimes it will be simpler to consider a smaller variant where we only keep the negative-degree elements. This is called **connective  $K$ -theory**, and is denoted  $ku^*$  (for complex  $K$ -theory) or  $ko^*$  (for real  $K$ -theory). These are also multiplicative. ◀

**Example 2.7** (Bordism). Let  $X$  be a space and define  $\Omega_n^O(X)$  to be the set of equivalence classes of maps of  $n$ -manifolds  $M \rightarrow X$ , where  $[f_0: M \rightarrow X] \sim [f_1: N \rightarrow X]$  if there’s a cobordism  $Y: M \rightarrow N$  and a map  $F: Y \rightarrow X$  extending  $f_0$  and  $f_1$ . This is an abelian group under disjoint union, and the collection  $\{\Omega_n^O\}$  defines a generalized homology theory called **unoriented bordism**.<sup>6</sup>

The following theorem was the beginning of differential topology.

**Theorem 2.8** (Thom). As graded abelian groups,  $\Omega_n^O(\text{pt}) \cong \mathbb{F}_2[x_2, x_4, x_5, x_6, \dots] = \mathbb{F}_2[x_i \mid i \neq 2^j - 1]$ . Moreover,  $\Omega_*^O$  is a direct sum of (suspended) ordinary cohomology theories.

There’s a lot of variations, based on whatever flavors of manifolds you consider. Using oriented manifolds produces **oriented bordism**  $\Omega_*^{\text{SO}}$ , spin manifolds produce **spin bordism**  $\Omega_*^{\text{Spin}}$ , and so forth. These are not direct sums of ordinary cohomology theories in general. ◀

<sup>5</sup>Extending from compact Hausdorff spaces to all of  $\mathbf{Top}$  is possible, but then one loses the vector-bundle-theoretic description.

<sup>6</sup>The corresponding cohomology theory is called **cobordism**.

**2.1. The definition.** Recall that if  $X$  is a CW complex, it has a **CW filtration** in which  $X_n$  is the  $n$ -**skeleton**, the union of all cells of dimension  $\leq n$ . Then,  $X_n/X_{n-1}$  is a wedge of  $n$ -spheres indexed by the  $n$ -cells of  $X$ . Using this formalism we can define some spectral sequences.

**Definition 2.9.**

- Let  $E_*$  be a generalized homology theory and  $X$  be a CW complex. Then, the CW filtration on  $X$  induces a spectral sequence of homological type that strongly converges, called the **Atiyah-Hirzebruch spectral sequence**:

$$E_{p,q}^2 = H_p(X; E_q(\text{pt})) \implies E_{p+q}(X).$$

- Let  $E^*$  be a generalized cohomology theory and  $X$  be a CW complex. Then, the CW filtration on  $X$  induces a spectral sequence of cohomological type that *conditionally* converges, called the **Atiyah-Hirzebruch spectral sequence**:

$$E_2^{p,q} = H^p(X; E^q(\text{pt})) \implies E^{p+q}(X).$$

**Calculations.**

**Example 2.10.** We'll use the Atiyah-Hirzebruch spectral sequence to compute  $K^*(\mathbb{CP}^n)$ . Recall that

$$H^p(\mathbb{CP}^k; A) = \begin{cases} A, & p \text{ even} \\ 0, & \text{odd.} \end{cases}$$

Hence

$$E_2^{p,q} = \begin{cases} \mathbb{Z}, & p, q \text{ even, } 0 \leq p \leq 2k \\ 0, & \text{otherwise.} \end{cases}$$

Thus all the differentials are zero! So  $E_2^{p,q} \cong E_\infty^{p,q}$ . Hence the  $E_\infty$  page has no torsion, and therefore  $K^*(\mathbb{CP}^n)$  is isomorphic to its associated graded.

$$K^i(\mathbb{CP}^n) = \begin{cases} \mathbb{Z}^{n+1}, & i \text{ even} \\ 0, & \text{otherwise.} \end{cases} \quad \blacktriangleleft$$

**Exercise 2.11.** Let  $\Sigma$  be a genus- $g$  orientable closed surface. Compute  $K^*(\Sigma_g)$ .

**Exercise 2.12.** What changes when you replace  $K^*$  with  $KO^*$ ?

### 3. THE SERRE SPECTRAL SEQUENCE AND COMPUTATIONS: 5/10/17

Today, Ernie spoke on the Serre spectral sequence and some other topics.

**Multiplicative structures.** So far, everything we've done has been graded modules over a ring  $R$ , and often  $R = \mathbb{Z}$ , so we're thinking about graded abelian groups. Recall that a **graded  $R$ -module** is an  $R$ -module

$$M_\bullet = \bigoplus_{i \in \mathbb{Z}} M_i.$$

If  $x \in M_i$ , we say its **degree** is  $i$ , and write  $|x| = i$ .

Graded modules are great, as they resemble homology of spaces. Cohomology has additional structure in the form of a cup product: if  $x \in H^i(X)$  and  $y \in H^j(X)$ , their cup product, denoted  $x \smile y$  or just  $xy$ , is a class in  $H^{i+j}(X)$ , and  $xy = (-1)^{ij}yx$ . This structure is axiomatized as a graded algebra.

**Definition 3.1.** A **graded  $R$ -algebra**  $M_\bullet$  is a graded  $R$ -module together with a **multiplication map**  $\mu: M_\bullet \times M_\bullet \rightarrow M_\bullet$  such that

- $\mu(M_i, M_j) \subseteq M_{i+j}$  and
- if  $|x| = i$  and  $|y| = j$ , then  $\mu(x, y) = (-1)^{ij}(X)$ .

The structure of (a page of) a spectral sequence fits into something called a differential graded module.

**Definition 3.2.**

- A **bigraded  $R$ -module** is an  $R$ -module  $M_{\bullet,\bullet}$  admitting a decomposition

$$M_{\bullet,\bullet} = \bigoplus_{i,j \in \mathbb{Z}} M_{i,j}.$$

The **total degree** of an  $x \in M_{i,j}$ , denoted  $|x|$ , is  $i + j$ . This degree turns  $M_{\bullet,\bullet}$  into a singly graded  $R$ -module; this grading is called the **total grading**.

- A **differential graded  $R$ -module** is a bigraded  $R$ -module  $M_{\bullet,\bullet}$  together with a map  $d: M_{\bullet,\bullet} \rightarrow M_{\bullet,\bullet}$  such that  $d^2 = 0$  and  $d$  shifts the total grading by either 1 (if  $M_{\bullet,\bullet}$  is graded cohomologically) or  $-1$  (if it's graded homologically).
- A **differential graded  $R$ -algebra** (DGA) is a differential graded  $R$ -module  $M_{\bullet,\bullet}$  together with a multiplication map making  $M_{\bullet,\bullet}$  a graded  $R$ -algebra with respect to the total grading and such that for all  $x, y \in M_{\bullet,\bullet}$ ,

$$d(xy) = d(x)y + (-1)^{|x|}xd(y).$$

The multiplicative structure in cohomology is very useful: it forces a lot of information, and also can be directly useful, e.g. showing that  $\mathbb{CP}^2$  and  $S^2 \vee S^4$  aren't homotopic, even though they have the same homology. Similarly, a multiplicative structure on a spectral sequence will force a lot of differentials, so is an awesome thing to have in your pocket if you want to compute things with spectral sequences.

**Definition 3.3.** A **multiplicative spectral sequence** is a spectral sequence  $E_2^{\bullet,\bullet} \Rightarrow M_{\bullet}$  such that the pages  $E_r^{\bullet,\bullet}$  are DGAs with respect to the grading and differential from the spectral sequence,  $M_{\bullet}$  is a graded algebra, and the convergence reflects the multiplicative structure.

**The Serre spectral sequence.**

**Definition 3.4.** A **(Serre) fibration**  $f: E \rightarrow X$  of topological spaces is a map such that if  $\Delta^n$  denotes the  $n$ -simplex and one has commuting maps

$$\begin{array}{ccc} \Delta^n \times \{0\} & \longrightarrow & E \\ \downarrow & & \downarrow f \\ \Delta^n \times [0, 1] & \longrightarrow & X, \end{array}$$

there exists a map  $G: \Delta^n \times [0, 1] \rightarrow E$  that commutes with the maps in the diagram.

We always take  $X$  to be path-connected, in which case  $f^{-1}(x) \simeq f^{-1}(x')$  for all  $x, x' \in X$ . This preimage is called the **fiber** of  $f$ , and is often denoted  $F$ ; the triple  $F \rightarrow E \rightarrow X$  is called a **fiber sequence**. We will also assume  $X$  is simply connected, which will allow us to obtain stronger results.

**Example 3.5.** Let  $M$  be a manifold of dimension  $n$ . Then,  $TM \rightarrow M$  is a fibration, and the fiber is  $\mathbb{R}^n$ . ◀

**Theorem 3.6** (Serre). *Fix a coefficient ring  $R$ ; let  $f: E \rightarrow X$  be a fibration and  $F$  be its fiber. Then, there exists a multiplicative spectral sequence, called the **Serre spectral sequence***

$$E_2^{p,q} = H^p(X; H^q(F; R)) \Longrightarrow H^{p+q}(E; R).$$

*Proof sketch.* Let  $\{X_i\}$  be the CW filtration of  $X$ , and let  $E_i := f^{-1}(X_i)$ , which induces an exhaustive filtration  $\{E_i\}$  of  $E$ . Applying  $H^q(-; R)$  defines a spectral sequence by the formalism from the first lecture. The multiplicative structure comes from the cup product on  $X$ . ◻

*Remark.* Let  $A$  be a multiplicative generalized cohomology theory (e.g.  $K$ -theory). Then, we could have applied  $A$  instead of  $H^q(-; R)$  and obtained a multiplicative spectral sequence

$$E_2^{p,q} = H^p(X; A^q(F)) \Longrightarrow A^{p+q}(E).$$

Letting  $A = H^*(-, R)$ , we recover the Serre spectral sequence, and letting  $E \rightarrow X$  be the identity map  $X \rightarrow X$ , which is a fibration, we recover the Atiyah-Hirzebruch spectral sequence. For this reason this spectral sequence is sometimes called the **Serre-Atiyah-Hirzebruch spectral sequence**. ◀

**Example 3.7.** Let  $PX := \text{Top}_*(I, X)$  denote the **path space**, i.e. the maps from the unit interval to  $X$ . Evaluation at 0 defines a map  $\text{ev}: PX \rightarrow X$ . The path space is made of spaghetti, hence is contractible: shrink each path from time 1 to time  $t$ , and let  $t \rightarrow 0$ .

$\text{ev}: PX \rightarrow X$  is a fibration, and the fiber is  $\Omega X$ , the space of (based) loops in  $X$  (i.e. based maps  $S^1 \rightarrow X$ ). Recall that a fiber sequence induces a long exact sequence in homotopy groups:

$$\cdots \longrightarrow \pi_n(F) \longrightarrow \pi_n(E) \longrightarrow \pi_n(X) \longrightarrow \pi_{n-1}(F) \longrightarrow \cdots \quad (3.8)$$

Since  $\pi_n(PX) = 0$ , this implies  $\pi_n(X) \cong \pi_{n-1}(\Omega X)$ .

Let's apply the Serre spectral sequence to this fibration in the case where  $R = \mathbb{Q}$  and  $X = S^3$ . The Serre spectral sequence takes the form

$$E_2^{p,q} = H^p(S^3; H^q(\Omega S^3; \mathbb{Q})) \implies H^{p+q}(PS^3; \mathbb{Q}).$$

We know the  $E_\infty$  page already: it's 0 unless  $p+q=0$ , in which case it's  $\mathbb{Q}$ . So we're going to reverse-engineer the spectral sequence, to use the  $E_\infty$  page to compute the  $E_2$  page.

We also know  $H^*(S^3; \mathbb{Q}) = E_{\mathbb{Q}}(X)$ , where  $|x| = 3$ , an exterior algebra in one variable. This is also isomorphic to  $\mathbb{Q}[x]/x^2$ , so has a  $\mathbb{Q}$  in degrees 0 and 3, and is 0 elsewhere.

We know  $H^0(\Omega S^3; \mathbb{Q}) = \mathbb{Q}$ , so the  $E_2$  page looks like

|   |   |   |   |     |
|---|---|---|---|-----|
| 3 | ? |   |   | ?   |
| 2 | ? |   |   | ?   |
| 1 | ? |   |   | ?   |
| 0 | 1 |   |   | $x$ |
|   | 0 | 1 | 2 | 3   |

with the missing entries equal to 0.

We know that the  $(3, 0)$  term has to vanish by the  $E_\infty$  page, so it either **supports a differential** (has a nonzero differential mapping out of it) or **receives a differential** (has a nonzero differential mapping into it). Since this is a first-quadrant spectral sequence, all differentials out of  $x$  hit 0, so it has to receive a differential. But on the  $E_2$  page, this differential comes from the 0 in position  $(1, 1)$ , so it's zero, and any differentials in page 4 or above mapping into  $x$  come from the fourth quadrant, so there has to be a nonzero differential on the  $E_3$  page mapping into  $x$ , so there's some  $y \in E_2^{0,2}$ , which generates a copy of  $\mathbb{Q}$ , such that  $d_3 y = x$ . There can't be more than one generator in  $E_2^{0,2}$ , because then either it would survive to the  $E_\infty$  page (which can't happen), or it gets killed, meaning the difference of it and  $y$  is not killed by  $d_3$  and hence survives. Oops. Thus,  $E_2^{0,2} = H^2(\Omega S^3; \mathbb{Q}) \cong \mathbb{Q}$ . Hence we know  $E_2^{3,2} = H^3(S^3; \mathbb{Q})$  as well, and the spectral sequence looks like

|   |     |   |   |              |
|---|-----|---|---|--------------|
| 2 | $y$ |   |   | $\mathbb{Q}$ |
| 1 | ?   |   |   | ?            |
| 0 | 1   |   |   | $x$          |
|   |     | 0 | 1 | 2            |
|   |     |   |   | 3            |

$d_3$

We can also immediately determine  $E_2^{\bullet,2}$ : looking at  $E_2^{0,2}$ , there are no differentials that hit something nonzero, or map from something nonzero to it. So anything in it survives to the  $E_\infty$  page, and hence it must be zero. Thus  $H^1(\Omega S^3; \mathbb{Q}) = 0$  and hence  $E_2^{1,3} = 0$  too.

The multiplicative structure tells us that the generator of  $E_2^{3,2}$  must be  $y \cdot x$ . Thus, the spectral sequence looks like

But now  $yx$  has to die, and the only way that can happen is if it's hit by  $d_3$  of the  $E_2^{0,4}$  term, which turns out to be  $y^2$ . This is because  $d_3 y = x$ , so

$$d_3(y^2) = d_3(y)y + (-1)^2 y d_3(y) = 2xy.$$

Thus  $d_3$  is multiplication by 2. Hence the spectral sequence looks like

But now we need  $y^2 x$  to vanish, and it's hit by  $y^3 \in E_2^{0,6}$  via  $d_3$ , which is multiplication by 3, and so on. Inductively we can conclude that

$$H^*(\Omega S^3; \mathbb{Q}) \cong \begin{cases} \mathbb{Q}, & n \text{ even} \\ 0, & n \text{ odd.} \end{cases}$$

Much of this argument, but not all of it, works with  $\mathbb{Q}$  replaced by  $\mathbb{Z}$ . The difference is that multiplication by 2, 3, etc. is not an isomorphism, so we have a sequence of generators  $y_1, y_2, \dots$ :

Now we have to figure out the multiplicative structure. We know  $y_1^2 = c_1 y_2$  for some  $c_1 \in \mathbb{Z}$ , so since  $d_3$  is an isomorphism, let's compute: we know  $d_3(y_2) = y_1 x$  by construction, and  $d_3(y_1^2) = 2y_1 x$  for the same reason as over  $\mathbb{Q}$ , so  $y_1^2 = 2y_2$ .

A similar calculation in general shows that  $y_1^n = n! y_n$ , as

$$\begin{aligned} d_3(y_1^n) &= d_3(y_1 y_1^{n-1}) = d_3(y_1) y_1^{n-1} + y_1 (n-1)! d(y_1^{n-1}) \\ &= x y_1^{n-1} + y_1 (n-1)! x y_{n-2} \\ &= x(n-1)! y_{n-1} + (n-1) y_{n-1} x (n-1)! \\ &= n! x y_{n-1}, \end{aligned}$$

but  $d_3(n! y_n) = n! x y_{n-1}$ . Hence the ring structure on  $H^*(\Omega S^3)$  is a divided power algebra.

**Definition 3.9.** A **divided power algebra** on a single generator  $x$  in degree  $k$ , denoted  $\Gamma(x)$ , is the free algebra generated by  $\{x_i\}_{i \geq 1}$  where  $|x_i| = ki$ , subject to the relations

$$x_i x_{i+j} = \binom{i+j}{j} x_{i+j} \quad \text{and} \quad x_i = \frac{x^i}{i!}.$$

Thus  $H^*(\Omega S^3) \cong \Gamma(y)$  with  $|y| = 2$ . ◀

**Exercise 3.10.** The same argument works to compute  $H^*(\Omega S^{2n+1})$ . Work it out for  $H^*(\Omega S^{2n})$ , which behaves differently.

**Example 3.11.** Let  $K(G, n)$  be an **Eilenberg-Mac Lane space**, i.e. a space with  $\pi_n(K(G, n)) = G$  and all other homotopy groups vanishing. It's a theorem that these exist for all  $n$  and  $G$  (abelian when  $n \geq 2$ ), and any two choices of a  $K(G, n)$  are homotopy equivalent for given  $G$  and  $n$ . For a simple example,  $S^1$  is a  $K(\mathbb{Z}, 1)$ , and for a less simple example,  $\mathbb{CP}^\infty$  is a  $K(\mathbb{Z}, 2)$ .

Eilenberg-Mac Lane spaces with  $n \geq 3$  are usually much harder to describe explicitly, but we can use the Serre spectral sequence to compute their cohomology. (3.8) tells us that  $\Omega K(G, n)$  has  $\pi_{n-1}(\Omega K(G, n)) = G$  and all other homotopy groups vanishing, so it's a model of  $K(G, n-1)$  (here we need  $n > 1$ ). Thus, the path space fibration is a fibration

$$K(G, n-1) \longrightarrow * \longrightarrow K(G, n).$$

This is useful for understanding **cohomology operations**, maps  $H^n(-, \mathbb{Z}) \rightarrow H^p(-, \mathbb{Z})$ , e.g.  $x \mapsto x^2$ . Since Eilenberg-Mac Lane spaces represent ordinary cohomology, these are parameterized by  $[K(\mathbb{Z}, n), K(\mathbb{Z}, p)] = H^p(K(\mathbb{Z}, n))$ .  $\blacktriangleleft$

$$U_{n-1} \longrightarrow U_n \longrightarrow S^{2n-1}.$$

Next let's consider  $n = 2$ .  $H^*(S^3) = E(x_3)$ , where  $|x_3| = 3$ , so by the Künneth formula,  $H^*(U_1, H^*(S^3)) = H^*(S^1) \otimes H^*(S^3) = E(x_1) \otimes E(x_3)$ , and this is the  $E_2$  page, with multiplicative structure.

|   |       |   |   |          |
|---|-------|---|---|----------|
| 1 | $x_1$ |   |   | $x_1x_3$ |
| 0 | 1     |   |   | $x_3$    |
|   | 0     | 1 | 2 | 3        |

**Example 3.13.** We can apply this computation of the cohomology of  $U_n$  to obtain the cohomology of its classifying space  $BU_n$ . This is the quotient of a contractible space  $EU_n$  by a free  $U_n$ -action (again, it's a theorem that this exists, and that any two choices are homotopy equivalent). Hence we get a fiber sequence  $U_n \rightarrow * \rightarrow BU_n$ .<sup>7</sup>

$$d(x_1 y_2^k) = y_2 y_2^k + (-1)x_1(0) = y_2^{k+1}.$$
$$\begin{array}{ccccccc}
x_5 & & & & & & \\
x_1 x_3 & & & & & & \\
x_3 & & x_3 y_2 & & & & \\
x_1 & \searrow^{d_2} & x_1 y_2 & \searrow^{d_2} & x_1 y_2^2 & \searrow^{d_2} & \dots \\
1 & 0 & y_2 & 0 & y_2^2 & & \dots \\
0 & 1 & 2 & 3 & 4 & & 
\end{array}$$

<sup>7</sup>This works for any Lie group  $G$ : we get a sequence  $G \rightarrow EG \rightarrow BG$ .

can also compute that  $d_2(x_1x_3) = y_2x_3$  using the Leibniz rule, so we have

$$\begin{array}{ccccccc}
 & & x_5 & & & & \\
 & & & & & & \\
 x_1x_3 & \xrightarrow{d_2} & x_3y_2 & & & & \\
 x_3 & \searrow d_3 & & & & & \\
 x_1 & \xrightarrow{d_2} & x_1y_2 & \xrightarrow{d_2} & x_1y_2^2 & \xrightarrow{d_2} & \cdots \\
 1 & 0 & y_2 & 0 & y^4, y_2^2 & & \cdots \\
 0 & 1 & 2 & 3 & 4 & & 
 \end{array}$$

If we continue this, we inductively get generators  $y_i \in H^{2i}(BU_n)$ , and we'll see that  $d(x_iy_{i+1}^k) = y_i^{k+1}$ , so there are no relations. Hence  $H^*(BU_n) \cong \mathbb{Z}[y_2, y_4, y_6, \dots, y_n]$ . One application of this is to characteristic classes:  $y_{2m}$  is better known as  $c_m$ , the  $m^{\text{th}}$  **Chern class** for complex vector bundles. ◀

**Example 3.14.** Let  $M$  be a manifold, which we'll assume to be simply connected. Let  $S(M) \rightarrow M$  be the unit sphere bundle inside the tangent bundle.<sup>8</sup> This is a **spherical fibration**, meaning a fibration whose fiber is a sphere. Since the cohomology of a sphere is very simple, the Serre spectral sequence allows us to calculate  $H^*(S(M))$ .

The fibration is  $S^{n-1} \rightarrow S(M) \rightarrow M$ , so the  $E_2$  page is a copy of  $H^*(M)$  in row 0 and a copy in row  $n-1$ . One can show that if  $x_{n-1} \in E_2^{0, n-1}$  is the generator, then the first and only supported differential is  $d_n(x_{n-1}) = \chi(M) \cdot [M]$ . You can use this to compute the  $E_\infty$  page. ◀

#### 4. THE EILENBERG-MOORE SPECTRAL SEQUENCE: 5/11/17

Today, Richard spoke on the Eilenberg-Moore spectral sequence, and through it a lot of homological algebra, including the Künneth theorem and derived functors.

Last time, Ernie told us about the Serre spectral sequence, which is associated to a fibration  $F \rightarrow E \rightarrow B$  and converges strongly if  $B$  is simply connected (so we don't have to worry about the  $\pi_1(B)$ -action on  $E$ ). The Eilenberg-Moore spectral sequence is a generalization.

Let  $F \rightarrow E \rightarrow B$  be a fibration and  $f: X \rightarrow B$  be a fibration. If  $E \times_B X$  denotes the pullback of  $E \rightarrow B$  by  $f$ , then  $E \times_B X \rightarrow X$  is a fibration with fiber  $F$ , i.e. we have a diagram of fiber sequences

$$\begin{array}{ccc}
 F & \xlongequal{\quad} & F \\
 \downarrow & & \downarrow \\
 E \times_B X & \xrightarrow{\quad} & E \\
 \downarrow \lrcorner & & \downarrow \pi \\
 X & \xrightarrow{f} & X.
 \end{array} \tag{4.1}$$

There are two versions of the Eilenberg-Moore spectral sequence, one for homology and one for cohomology; they're very similar, so we'll only discuss the cohomology one today. If  $R$  is a ring, it will be a spectral sequence that, given  $H^*(E; R)$ ,  $H^*(X; R)$ ,  $H^*(E; R)$ , and  $\pi^*$  and  $f^*$ , computes  $H^*(E \times_B X; R)$ .

*Remark.* Suppose  $X = B$  and  $f = \text{id}$ . Then, the Eilenberg-Moore spectral sequence will reduce to the Serre spectral sequence. ◀

Suppose  $B$  is a point, so the fibration is  $E \rightarrow E \rightarrow *$ , so  $f$  is the crush map. Then (4.1) asks how to compute  $H^*(E \times X; R)$  in terms of  $H^*(X; R)$  and  $H^*(E; R)$ . This reduces to a preexisting result in algebraic topology called the **Künneth formula**.

<sup>8</sup>This requires a choice of a Riemannian metric to construct it, but the resulting bundle does not depend on the choice of metric.

**Theorem 4.2** (Künneth). *Let  $k$  be a field and  $E$  and  $X$  be topological spaces. Then, there is an isomorphism*

$$H^*(E; k) \otimes_k H^*(X; k) \xrightarrow{\cong} H^*(E \times X; k).$$

The map can be made explicit: let  $\pi_1: E \times X \rightarrow E$  and  $\pi_2: E \times X \rightarrow X$  be the projections. By universal property of the coproduct (which is the tensor product for rings), we get a map  $\pi_1^* \otimes \pi_2^*: H^*(E; k) \otimes_k H^*(X; k) \rightarrow H^*(E \times X; k \otimes k)$ , and then can push forward along multiplication  $k \otimes k \rightarrow k$  to obtain a map  $H^*(E \times X; k \otimes k) \rightarrow H^*(E \times X; k)$ . In symbols,  $x, y \mapsto \pi_1^*(x) \smile \pi_2^*(y)$ . More generally there's a Künneth spectral sequence.

The universal coefficient theorem encodes another important piece of homological algebra. If we know  $H_n(X; \mathbb{Z})$  and want to understand  $H_n(X; A)$  (where  $A$  is an abelian group), we would like it to just be  $H_n(X; \mathbb{Z}) \otimes A$ , but this isn't always true, and fails when  $- \otimes A$  is not exact. So we get a leftover term.

**Theorem 4.3** (Universal coefficient theorem). *Let  $C_\bullet$  be a chain complex and  $H_n(C_\bullet; A) := H_n(C_\bullet \otimes A)$ . Then, there is a short exact sequence*

$$0 \longrightarrow H_n(C_\bullet) \otimes A \longrightarrow H_n(C_\bullet; A) \longrightarrow \text{Tor}^1(H_{n-1}(C_\bullet), A) \longrightarrow 0.$$

Here,  $\text{Tor}_R^n(-, A)$  is the  $n^{\text{th}}$  **derived functor** of  $- \otimes_R A$ . When  $A = \mathbb{Z}$ ,  $\text{Tor}_{\mathbb{Z}}^n(-, A) = 0$  for  $n > 1$ , and for this reason,  $\text{Tor}_{\mathbb{Z}}^1$  is sometimes just denoted  $\text{Tor}$ .

Let's go into this for a little bit. Suppose we have a short exact sequence of  $R$ -modules

$$0 \longrightarrow X \longrightarrow Y \longrightarrow Z \longrightarrow 0.$$

If  $A$  is another  $R$ -module,  $- \otimes_R A$  is right exact, but in general not left exact, so we only have the sequence

$$X \otimes_R A \longrightarrow Y \otimes_R A \longrightarrow Z \otimes_R A \longrightarrow 0. \quad (4.4)$$

We'd like to measure how badly this fails to be left exact, and  $\text{Tor}_R^n$  does this. Specifically, it extends (4.4) into a long exact sequence

$$\cdots \rightarrow \text{Tor}_R^2(Z, A) \rightarrow \text{Tor}_R^1(X, A) \rightarrow \text{Tor}_R^1(Y, A) \rightarrow \text{Tor}_R^1(Z, A) \rightarrow X \otimes_R A \rightarrow Y \otimes_R A \rightarrow Z \otimes_R A \rightarrow 0.$$

So how can you compute this? The first step is to take a **projective resolution**, a long exact sequence

$$\cdots \longrightarrow P_{-3} \longrightarrow P_{-2} \longrightarrow P_{-1} \longrightarrow P_0 \longrightarrow X \longrightarrow 0$$

such that each  $P_i$  is projective.<sup>9</sup> Now, apply  $- \otimes_R A$  to get a sequence which is not necessarily exact, but the composition of any two maps is zero:

$$\cdots \longrightarrow P_{-2} \otimes_R A \longrightarrow P_{-1} \otimes_R A \longrightarrow P_0 \otimes_R A \longrightarrow X \otimes_R A \longrightarrow 0.$$

Call this complex  $P_\bullet \otimes_R A$ .

**Definition 4.5.** The  $n^{\text{th}}$  **Tor group** is

$$\text{Tor}_R^n(X, A) := H_{-n}(P_\bullet \otimes_R A).$$

It's important to prove that this doesn't depend on your choice of projective resolution. It's also possible to resolve  $A$  instead of resolving  $X$ , and this produces isomorphic Tor groups.

*Remark.* Any module over a principal ideal domain has a two-term free resolution, hence also a projective resolution:

$$0 \longrightarrow F_{-1} \longrightarrow F_0 \longrightarrow A \longrightarrow 0.$$

Here,  $F_0$  is free on the generators of  $A$ , and  $F_{-1}$  is free on the relations between those generators, with the map encoding this. ◀

Using this, one has a more powerful version of the Künneth theorem.

---

<sup>9</sup>The category of  $R$ -modules **has enough projectives**, meaning such a sequence always exists. In more general abelian categories, this isn't always the case.

**Theorem 4.6** (K nneth). *Let  $R$  be a PID and  $X$  and  $Y$  be spaces such that  $H^*(Y; R)$  is a finitely-generated, free  $R$ -module. Then, for all  $n$ , there's a short exact sequence*

$$0 \longrightarrow \bigoplus_{i+j=n} H_i(X; R) \otimes_R H_j(Y; R) \longrightarrow H_n(X \times Y; R) \longrightarrow \bigoplus_{i+j=n-1} \text{Tor}_R^1(H_i(X; R), H_j(Y; R)) \longrightarrow 0.$$

This is the degeneration of the Eilenberg-Moore spectral sequence for the fibration  $Y \rightarrow *$  and a crush map  $X \rightarrow *$ , so the pullback is just  $X \times Y$ . The requirement that  $R$  be a PID is what gives us the two-term free resolution, so that higher Tor vanishes, allowing the spectral sequence to degenerate.

**Theorem 4.7.** *Given a fibration  $F \rightarrow E \rightarrow B$  and a map  $f: X \rightarrow B$ , such that  $B$  is simply connected,<sup>10</sup> then there exists a second-quadrant spectral sequence*

$$E_2^{p,q} \cong \text{Tor}_{H^*(B; R)}^{p,q}(H^*(X; R), H^*(E; R)) \implies H^*(E \times_B X; R).$$

This Tor is over a DGA, which is new. Let  $\Gamma$  be a DGA and  $(M^\bullet, d_M)$  and  $(N^\bullet, d_N)$  be dg  $\Gamma$ -modules. By a **projective resolution** we mean a resolution of  $M^\bullet$  by projective dg  $\Gamma$ -modules

$$\cdots \longrightarrow P_{-2}^\bullet \longrightarrow P_{-1}^\bullet \longrightarrow P_0^\bullet \longrightarrow M^\bullet \longrightarrow 0,$$

i.e. a double complex

$$\begin{array}{ccccccc} & \vdots & & \vdots & & \vdots & & \vdots \\ & \uparrow d_{P_{-2}} & & \uparrow d_{P_{-1}} & & \uparrow d_{P_0} & & \uparrow d_M \\ \cdots & \longrightarrow & (P_{-2})^2 & \xrightarrow{\delta_2^2} & (P_{-1})^2 & \xrightarrow{\delta_1^2} & (P_0)^2 & \xrightarrow{\delta_0^2} & M^2 & \longrightarrow & 0 \\ & \uparrow d_{P_{-2}} & & \uparrow d_{P_{-1}} & & \uparrow d_{P_0} & & \uparrow d_M \\ \cdots & \longrightarrow & (P_{-2})^1 & \xrightarrow{\delta_2^1} & (P_{-1})^1 & \xrightarrow{\delta_1^1} & (P_0)^1 & \xrightarrow{\delta_0^1} & M^1 & \longrightarrow & 0 \\ & \uparrow d_{P_{-2}} & & \uparrow d_{P_{-1}} & & \uparrow d_{P_0} & & \uparrow d_M \\ \cdots & \longrightarrow & (P_{-2})^0 & \xrightarrow{\delta_2^0} & (P_{-1})^0 & \xrightarrow{\delta_1^0} & (P_0)^0 & \xrightarrow{\delta_0^0} & M^0 & \longrightarrow & 0. \end{array}$$

Using this, we can define the **total complex** or **totalization**, a *singly* graded DGA, to be

$$\text{Tot}((P_\bullet)^\bullet)_j := \bigoplus_{m+n=j} (P_m)^n,$$

with differential

$$\partial_j := \sum_{m+n=j} \delta_m^n + (-1)^m d_{P_{-m}}.$$

You can filter this in different ways, as long as you exhaust everything, e.g.

$$F_r^{-n} := \bigoplus_{\substack{i+j=r \\ i \geq -n}} (P_i)^j.$$

Now, we can define the bigraded Tor groups to be

$$\text{Tor}_\Gamma^{-i, \bullet}(M, N) := H^{-i, \bullet}(M \otimes_\Gamma \text{Tot}(P_\bullet)).$$

**The bar construction.** The way we actually calculate this is to use the bar construction. Fix a field  $k$  and a DGA  $\Gamma$ , and assume  $\Gamma$  is **connected**, i.e. the map  $\eta: k \rightarrow \Gamma$  is an isomorphism on degree-0 terms. Let  $\bar{\Gamma}$  denote the subalgebra of  $\Gamma$  generated by terms of positive degree,  $M$  be a right  $\Gamma$ -module, and  $N$  be a left  $\Gamma$ -module. Then, let

$$B^{-n}(M, \Gamma, N) := M \otimes_k \underbrace{\bar{\Gamma} \otimes_k \cdots \otimes_k \bar{\Gamma}}_{n \text{ copies}} \otimes_k N.$$

<sup>10</sup>More generally, we can allow  $B$  such that the action of  $\pi_1(B)$  on the fiber is trivial, like in the Serre spectral sequence.

For a  $\gamma \in \Gamma$ , let  $\bar{\gamma} := (-1)^{1+\deg(\gamma)}\gamma$ . Then, the differential is

$$\delta(m[\gamma_1 | \cdots | \gamma_n]n) := (-1)^{\deg m} \left( m \cdot \gamma_1[\gamma_2 | \cdots | \gamma_n]n + \sum_{i=1}^{n-1} (m[\bar{\gamma}_1 | \cdots | \bar{\gamma}_i \bar{\gamma}_{i+1} | \cdots | \bar{\gamma}_n]n) + m[\bar{\gamma}_1 | \cdots | \bar{\gamma}_{n-1}] \gamma_n n \right).$$

With this differential,  $B^\bullet(M, \Gamma, N)$  is a resolution for  $M \otimes_\Gamma N$ , and so

$$\mathrm{Tor}_\Gamma^{i,\bullet}(M, N) = H^i(B^\bullet(M, \Gamma, N)).$$

Let's use this to compute something.

**Example 4.8.** Let  $\Gamma = \Lambda(x)$  with  $|x| = m$ , i.e. an exterior algebra in a single variable. We want to compute  $\mathrm{Tor}_{\Lambda(x)}(k, k)$ .

$B^{-n}(k, \Lambda(x), k) = \bar{\Lambda}(x)^{\otimes n}$  is free in degree  $(-n, mn)$ , generated by  $[x | \cdots | x]$ . You can calculate that the differential is equal to 0, so passing to total degree, the homology is

$$\mathrm{Tor}_{\Lambda(x)}^{i,j}(k, k) = \begin{cases} k, & (i, j) = (r, m-1), \ r \geq 0 \\ 0, & \text{otherwise.} \end{cases}$$

Now let's feed this to the Eilenberg-Moore spectral sequence applied to the pullback

$$\begin{array}{ccc} \Omega S^{n+1} & \longrightarrow & PS^{n+1} \simeq * \\ \downarrow & & \downarrow \\ * & \longrightarrow & S^n. \end{array}$$

◀

**Example 4.9.** Another application which is harder with the Serre spectral sequence is to apply this to the fibration  $G/H \rightarrow BH \rightarrow BG$  when  $G$  is a Lie group and  $H$  is a normal closed subgroup. You can run the Serre spectral sequence here, but have to worry about local coefficients and other things that go bump in the night.

In particular, the  $E_2$  page is  $\mathrm{Tor}_{H^*(S^n, k)}^{\bullet, \bullet}(k, k)$ , which we just computed.

◀

Another application is to the Bökstedt spectral sequence for computing topological Hochschild homology  $THH(R) := R \otimes_{R \otimes_k R^{\mathrm{op}}}^{\mathbf{L}} R$ , where  $R$  is a ring spectrum.
